The TRDP Light Library API Specification

TCN *Open*

1.1 General Information

1.1.1 Purpose

The TRDP protocol has been defined as the standard communication protocol in IP-enabled trains. It allows communication via process data (periodically transmitted data using UDP/IP) and message data (client - server messaging using UDP/IP or TCP/IP) This document describes the light API of the TRDP Library.

1.1.2 Scope

The intended audience of this document is the developers and project members of the TRDP project. TRDP Client Applications are programs using the TRDP protocol library to access the services of TRDP. Programmers developing such applications are the main target audience for this documentation.

1.1.3 Related documents

1.1.4 Abbreviations and Definitions

-*API* Application Programming Interface

-*ECN* Ethernet Consist Network

-*TRDP* Train Real-time Data Protocol

-*TCMS* Train Control Management System

1.2 Terminology

The API documented here is mainly concerned with three bodies of code:

- *TRDP Client Applications* (or 'client applications' for short): These are programs using the API to access the services of TRDP. Programmers developing such applications are the main target audience for this documentation.
- *TRDP Light Implementations* (or just 'TRDP implementation'): These are libraries realising the API as documented here. Programmers developing such implementations will find useful definitions about syntax and semantics of the API within this documentation.
- *VOS Subsystem* (Virtual Operating System): An OS and hardware abstraction layer which offers memory, networking, threading, queues and debug functions. The VOS API is documented here.

The following diagram shows how these pieces of software are interrelated.

Figure 1.1 Sample client workflow

1.3 Conventions of the API

The API comprises a set of C header files that can also be used from client applications written in C++. These header files are contained in a directory named `trdp/api` and a subdirectory called `trdp/vos/api` with declarations not topical to TRDP but needed by the stack. Client applications shall include these header files like:

```
#include "trdp_if_light.h"
```

and, if VOS functions are needed, also the corresponding headers:

```
#include "vos_thread.h"
```

for example.

The subdirectory `trdp/doc` contains files needed for the API documentation.

Generally client application source code including API headers will only compile if the parent directory of the `trdp` directory is part of the include path of the used compiler. No other subdirectories of the API should be added to the compiler's include path.

The client API doesn't support a "catch-all" header file that includes all declarations in one step; rather the client application has to include individual headers for each feature set it wants to use.

5.11.1 Detailed Description

Functions for train topology information access.

The TTI subsystem maintains a pointer to the TAU_TTDB struct in the TRDP session struct. That TAU_TTDB struct keeps the subscription and listener handles, the current TTDB directories and a pointer list to consist infos (in network format). On init, most TTDB data is requested from the ECSP plus the own consist info. This data is automatically updated if an inauguration is detected. Additional consist infos are requested on demand, only.

5.22.2.4 trdp_pdDistribute()

```
TRDP_ERR_T trdp_pdDistribute (
    PD_ELE_T * pSndQueue )
```

Distribute send time of PD packets over time.

The duration of PD packets on a 100MBit/s network ranges from 3us to 150us max. Because a cyclic thread scheduling below 5ms would put a too heavy load on the system, and PD packets cannot get larger than 1432 (+ UDP header), we will not account for differences in packet size. Another factor is the differences in intervals for different packets: We should only change the starting times of the packets within 1/2 the interval time. Otherwise a late addition of packets could lead to timeouts of already queued packets. Scheduling will be computed based on the smallest interval time.

Parameters

in	<i>pSndQueue</i>	pointer to send queue
----	------------------	-----------------------

Return values

<i>TRDP_NO_ERR</i>	
--------------------	--

Here is the call graph for this function:

5.23.2.4 trdp_pdDistribute()

```
TRDP_ERR_T trdp_pdDistribute (
    PD_ELE_T * pSndQueue )
```

Distribute send time of PD packets over time.

The duration of PD packets on a 100MBit/s network ranges from 3us to 150us max. Because a cyclic thread scheduling below 5ms would put a too heavy load on the system, and PD packets cannot get larger than 1432 (+ UDP header), we will not account for differences in packet size. Another factor is the differences in intervals for different packets: We should only change the starting times of the packets within 1/2 the interval time. Otherwise a late addition of packets could lead to timeouts of already queued packets. Scheduling will be computed based on the smallest interval time.

Parameters

in	<i>pSndQueue</i>	pointer to send queue
----	------------------	-----------------------

Return values

<i>TRDP_NO_ERR</i>	
--------------------	--

Here is the call graph for this function:

    PD_ELEMENT * pElement,
    UINT32 sequenceCounter,
    TRDP_IP_ADDR_T srcIP,
    TRDP_MSG_T msgType )
```

check and update the sequence counter for the comID/source IP.

If the comID/srcIP is not found, update it and return 0 - else if already received, return 1 On memory error, return -1

Parameters

in	<i>pElement</i>	subscription element
in	<i>sequenceCounter</i>	sequence counter to check
in	<i>srcIP</i>	Source IP address
in	<i>msgType</i>	type of the message

Return values

0	- no duplicate 1 - duplicate or old sequence counter -1 - memory error

5.33.2 Macro Definition Documentation

5.33.2.1 VOS_MEM_BLOCKSIZEs

```
#define VOS_MEM_BLOCKSIZEs
```

Value:

```
{34u, 48u, 128u, 180u, 256u, 512u, 1024u, 1480u, 2048u, \
  4096u, 11520u, 16384u, 32768u, 65536u, 131072u}
```

We internally allocate memory always by these block sizes.

The largest available block is 524288 Bytes, provided the overall size of the used memory allocation area is larger.

5.33.2.2 VOS_MEM_PREALLOCATE

```
#define VOS_MEM_PREALLOCATE {0u, 0u, 0u, 0u, 0u, 0u, 0u, 0u, 4u, 0u, 0u, 0u, 0u, 0u, 0u}
```

Default pre-allocation of free memory blocks.

To avoid problems with too many small blocks and no large one. Specify how many of each block size that should be pre-allocated (and freed!) to pre-segment the memory area.

    VOS_SHRD_T handle,
    const UINT8 * pMemoryArea )

Close connection to the shared memory area.

If the area was created by the calling process, the area will be closed (freed). If the area was attached, it will be detached. This function is not available in each target implementation.

Parameters

in	<i>handle</i>	Returned handle
in	<i>pMemoryArea</i>	Pointer to memory area

    VOS_SHRD_T * pHandle,
    UINT8 ** ppMemoryArea,
    UINT32 * pSize )
```

Create a shared memory area or attach to existing one.

The first call with the a specified key will create a shared memory area with the supplied size and will return a handle and a pointer to that area. If the area already exists, the area will be opened. This function is not available in each target implementation.

Parameters

in	<i>pKey</i>	Unique identifier (file name)
