Chapter 1

The TRDP Light Library API Specification
1.1 General Information

1.1.1 Purpose

The TRDP protocol has been defined as the standard communication protocol in IP-enabled trains. It allows communication via process data (periodically transmitted data using UDP/IP) and message data (client - server messaging using UDP/IP or TCP/IP) This document describes the light API of the TRDP Library.

1.1.2 Scope

The intended audience of this document is the developers and project members of the TRDP project. TRDP Client Applications are programs using the TRDP protocol library to access the services of TRDP. Programmers developing such applications are the main target audience for this documentation.

1.1.4 Abbreviations and Definitions

-*API* Application Programming Interface -*ECN* Ethernet Consist Network -*TRDP* Train Real-time Data Protocol -*TCMS* Train Control Management System

1.2   Terminology

The API documented here is mainly concerned with three bodies of code:

- *TRDP Client Applications* (or 'client applications' for short): These are programs using the API to access the services of TRDP. Programmers developing such applications are the main target audience for this documentation.

- *TRDP Light Implementations* (or just 'TRDP implementation'): These are libraries realising the API as documented here. Programmers developing such implementations will find useful definitions about syntax and semantics of the API wihtin this documentation.

- *VOS Subsystem* (Virtual Operating System): An OS and hardware abstraction layer which offers memory, networking, threading, queues and debug functions. The VOS API is documented here.

1.3   Use Cases

The following diagram shows how these pieces of software are interrelated. Single threaded flow:
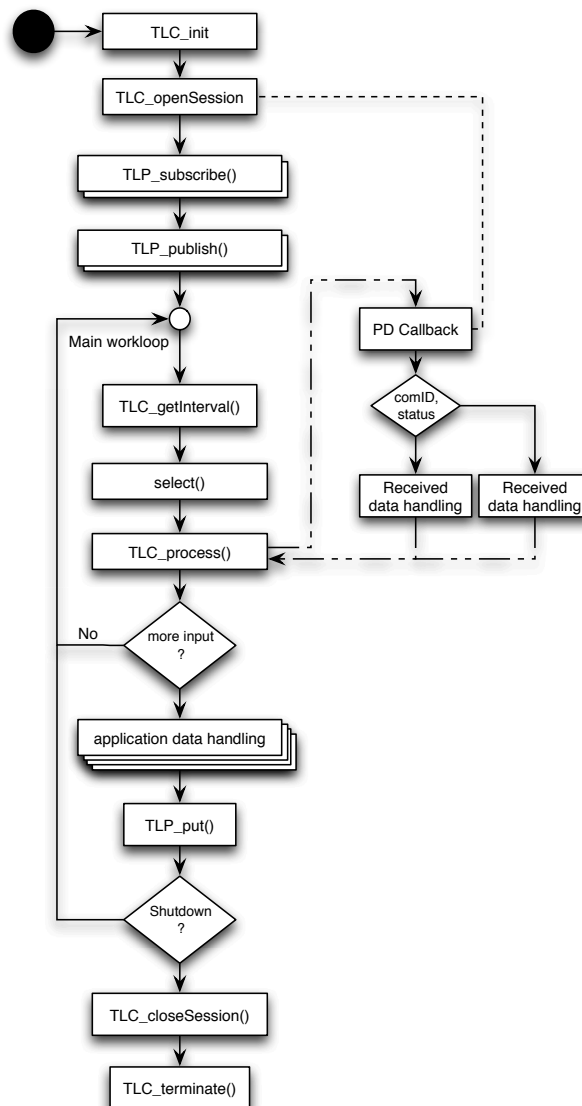

Figure 1.1 Sample client workflow (Single Thread)

Usage of the separate process handling (separate threads for PD and MD):
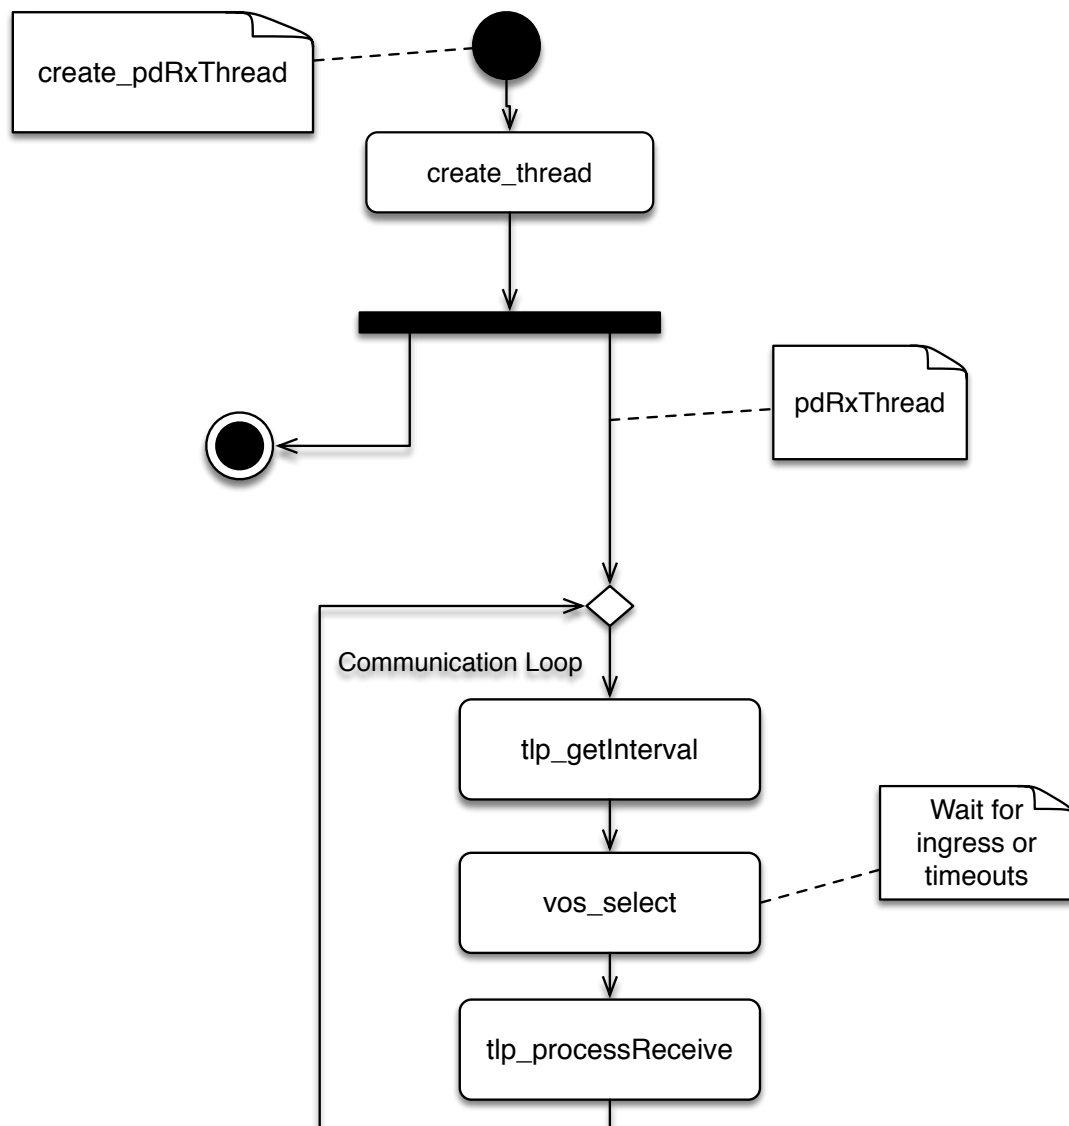

Figure 1.2 Multi-threaded processing of PD Reception

The transmit thread should be a cyclic thread. Cycle times down to 1ms are supported:
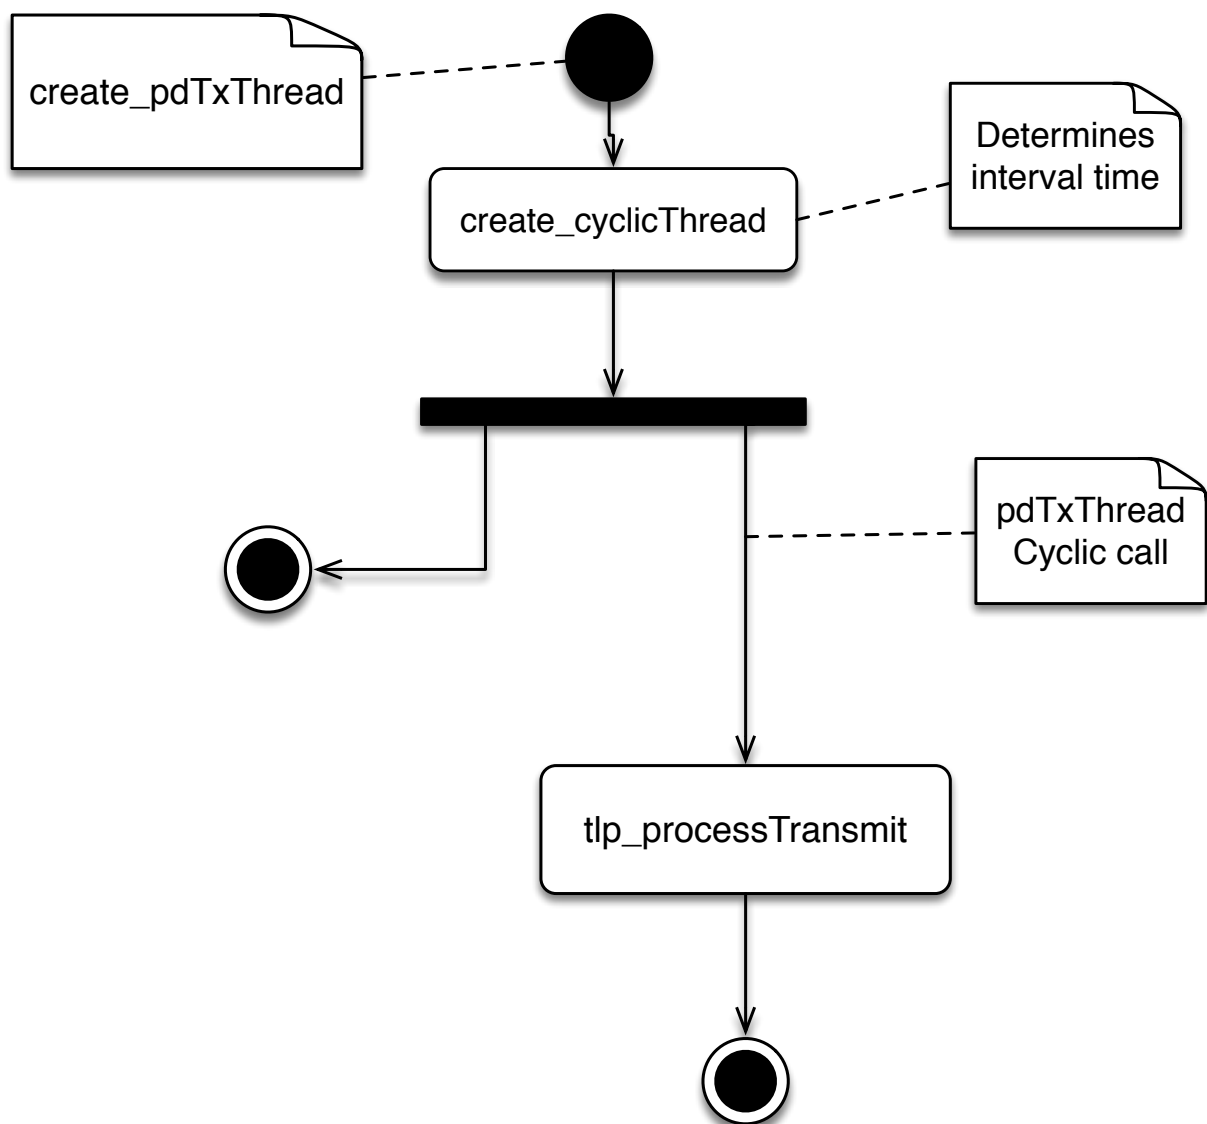

Figure 1.3 Multi-threaded processing of PD Transmit

If Message Data support is needed (MD_SUPPORT=1):
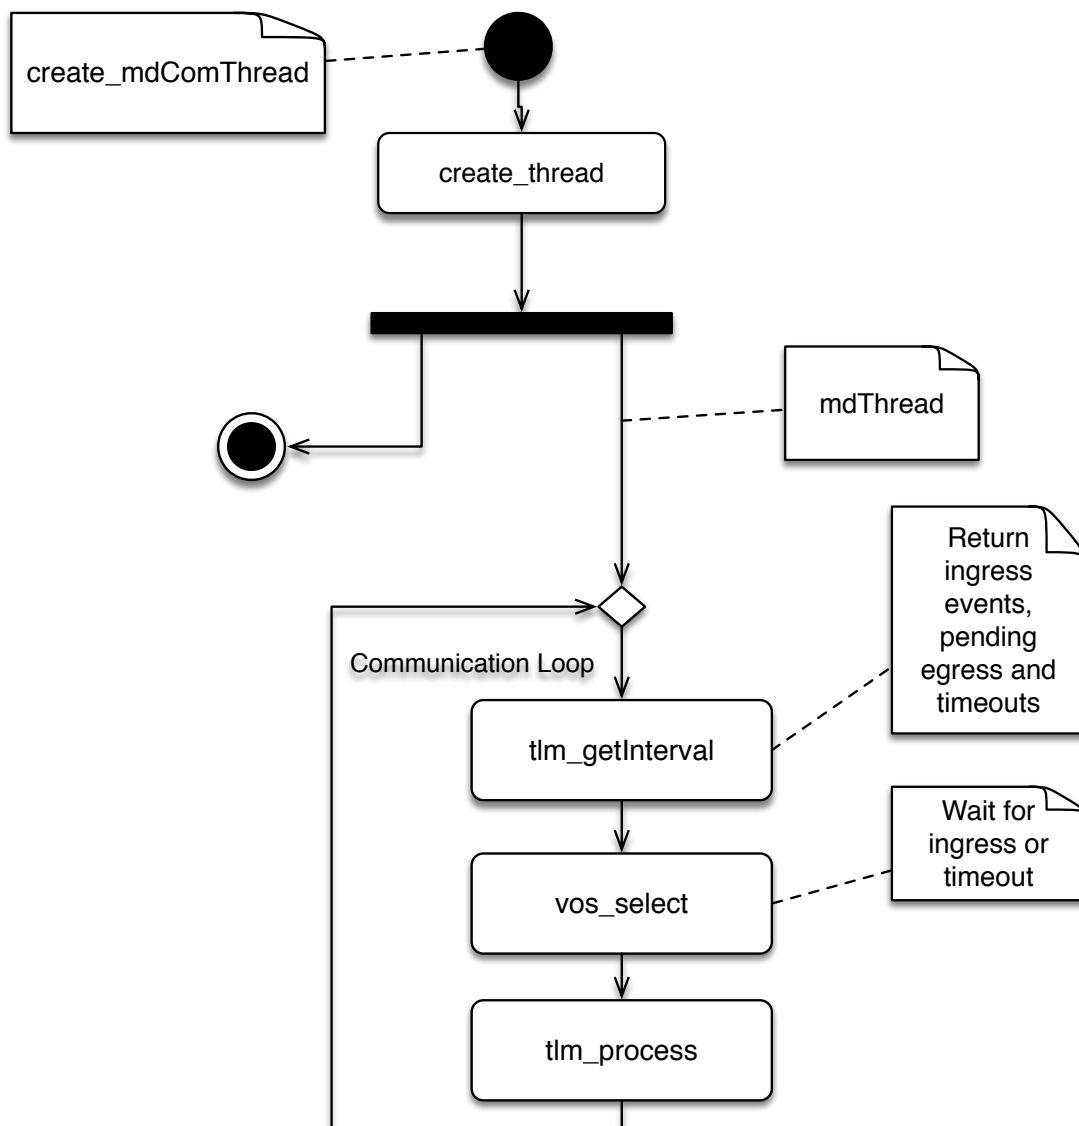

Figure 1.4 Multi-threaded processing of MD

Note: Mixed usage of the single threaded call tlc_process() with the multi-threaded calls tlm_process/tlp_process↩
Transmit/tlp_processReceive is not supported!

1.4 Conventions of the API

The API comprises a set of C header files that can also be used from client applications written in C++. These header files are contained in a directory named `trdp/api` and a subdirectory called `trdp/vos/api` with declarations not topical to TRDP but needed by the stack. Client applications shall include these header files like:

```
#include "trdp_if_light.h"
```

and, if VOS functions are needed, also the corresponding headers:

```
#include "vos_thread.h"
```

for example.

The subdirectory `trdp/doc` contains files needed for the API documentation.

Generally client application source code including API headers will only compile if the parent directory of the `trdp` directory is part of the include path of the used compiler. No other subdirectories of the API should be added to the compiler's include path.

The client API doesn't support a "catch-all" header file that includes all declarations in one step; rather the client application has to include individual headers for each feature set it wants to use.

Further description of the API and the usage of the TRDP protocol stack can be found in the TCNOpen TRDP User's Manual (at tcnopen.eu).

```
#include "vos_thread.h"
```

5.13.1 Detailed Description

Functions for train topology information access.

The TTI subsystem maintains a pointer to the TAU_TTDB struct in the TRDP session struct. That TAU_TTDB struct keeps the subscription and listener handles, the current TTDB directories and a pointer list to consist infos (in network format). On init, most TTDB data is requested from the ECSP plus the own consist info. This data is automatically updated if an inauguration is detected. Additional consist infos are requested on demand, only. Because of the asynchronous behavior of the TTI subsystem, most functions in tau_tti.c may return TRDP_N↩ ODATA_ERR on first invocation. They should be called again after 1...3 seconds (3s is the timeout for most MD replies).

5.21.2.1 tlp_get()

```
EXT_DECL TRDP_ERR_T tlp_get (

            TRDP_PD_INFO_T * pPdInfo,
            UINT8 * pData,
            UINT32 * pDataSize )
```

Get the last valid PD message.

This allows polling of PDs instead of event driven handling by callbacks

in	*subHandle*	the handle returned by subscription
in,out	*pPdInfo*	pointer to application's info buffer
in,out	*pData*	pointer to application's data buffer

            TRDP_FDS_T * pFileDesc,
            INT32 * pNoDesc )
```

Get the lowest time interval for PDs.

Return the maximum time interval suitable for 'select()' so that we can send due PD packets in time. If the PD send queue is empty, return zero time

Parameters

in	*appHandle*	The handle returned by tlc_openSession
out	*pInterval*	pointer to needed interval

Search the queue for pending PDs and MDs to be sent Search the receive queue for pending PDs and MDs (time out)

Note: If using tlc_process(), do not use tlp_process∗() and tlm_process() calls at the same time! Single thread usage -> use tlc_getInterval(), vos_select(), tlc_process() Multiple threads -> thread 1: use tlp_getInterval(), vos← _select(), tlp_processReceive() -> thread 2: cyclically call tlp_processSend() -> thread 3: use tlm_getInterval(), vos_select(), tlm_process() for message data

5.26.2.5 trdp_pdDistribute()

```
TRDP_ERR_T trdp_pdDistribute (
            PD_ELE_T * pSndQueue )
```

Distribute send time of PD packets over time.

The duration of PD packets on a 100MBit/s network ranges from 3us to 150us max. Because a cyclic thread scheduling below 5ms would put a too heavy load on the system, and PD packets cannot get larger than 1432 (+ UDP header), we will not account for differences in packet size. Another factor is the differences in intervals for different packets: We should only change the starting times of the packets within 1/2 the interval time. Otherwise a late addition of packets could lead to timeouts of already queued packets. Scheduling will be computed based on the smallest interval time.
Parameters

in	*pSndQueue*	pointer to send queue

Return values

TRDP_NO_ERR	

Here is the call graph for this function:

### 5.26.2.6   trdp_pdHandleTimeOuts()

5.41.2 Macro Definition Documentation

5.41.2.1 VOS_MEM_MAX_PREALLOCATE

```
#define VOS_MEM_MAX_PREALLOCATE 10u
```

We internally allocate memory always by these block sizes.

The largest available block is 524288 Bytes, provided the overal size of the used memory allocation area is larger. Max. no. of blocks to pre-allocate

5.41.2.2 VOS_MEM_PREALLOCATE

```
#define VOS_MEM_PREALLOCATE {0u, 0u, 0u, 0u, 0u, 0u, 0u, 4u, 0u, 0u, 0u, 0u, 0u, 0u, 0u}
```

Default pre-allocation of free memory blocks.

To avoid problems with too many small blocks and no large one. Specify how many of each block size that should be pre-allocated (and freed!) to pre-segment the memory area.

Close connection to the shared memory area.

If the area was created by the calling process, the area will be closed (freed). If the area was attached, it will be detached. This function is not available in each target implementation.

Parameters

in	*handle*	Returned handle
in	*pMemoryArea*	Pointer to memory area

Return values

VOS_NO_ERR	no error
VOS_MEM_ERR	no memory available

            UINT32 * pSize )
```

Create a shared memory area or attach to existing one.

The first call with the a specified key will create a shared memory area with the supplied size and will return a handle and a pointer to that area. If the area already exists, the area will be opened. This function is not available in each target implementation.

Parameters

in	*pKey*	Unique identifier (file name)

            UINT32 dataLen )
```

Calculate CRC for the given buffer and length.

For TRDP FCS CRC calculation the CRC32 according to IEEE802.3 with start value 0xffffffff is used. Note↩
: Returned CRC is inverted

Parameters

in	*crc*	Initial value.
in,out	*pData*	Pointer to data.
in	*dataLen*	length in bytes of data.

Return values

crc32	according to IEEE802.3

Calculate CRC for the given buffer and length.

/ to IEC 61375-2-3 A.3 Note: Returned CRC is inverted

Parameters

in	*crc*	Initial value.
in,out	*pData*	Pointer to data.
in	*dataLen*	length in bytes of data.

Return values

crc32	according to IEEE802.3

5.47.3.2 vos_getErrorString()

```
EXT_DECL const CHAR8* vos_getErrorString (
            VOS_ERR_T error )
```

Return a human readable error representation.

5.47.3.4 vos_getVersionString()

```
EXT_DECL const CHAR8* vos_getVersionString (
            void )
```

Return a human readable version representation.

Return string in the form 'v.r.u.b'

Return values

5.47.3.5 vos_hostIsBigEndian()

```
EXT_DECL int vos_hostIsBigEndian (
            void  )

```
EXT_DECL VOS_ERR_T vos_init (
            void * pRefCon,
            VOS_PRINT_DBG_T pDebugOutput )
```

Initialize the vos library.

This is used to set the output function for all VOS error and debug output.

Parameters

in	*pRefCon*	user context
in	*pDebugOutput*	pointer to debug output function

Return values

5.47.3.8 vos_terminate()

```
EXT_DECL void vos_terminate (
            void )
```

DeInitialize the vos library.

Should be called last after TRDP stack/application does not use any VOS function anymore.
